Self-Gravity in QM?

- The SN-equation
- Gravitational collapse
- Conclusions

- ▶ **Universality of Free Fall (UFF):** The space-time trajectory of a *test-particle* only depends on its initial position and velocity but not on its other (physical or chemical) attributes. This introduces a path structure on spacetime, though not necessarily that of geodesics with respect to a linear connection.
- ▶ **Local Lorentz Invariance (LLI):** The outcome of any local experiment is independent of the instantaneous orientation and velocity of the equipment (laboratory). In particular, there are no preferred-frame effects.
- ▶ **Universality of Clock Rates and Gravitational Redshift (UCR/UGR):** The rates of any two *standard clocks* agree if taken along the same worldline. If taken along different worldlines and intercompared, e.g., by means of electromagnetic signals, they differ by the standard ($\alpha = 0$) redshift formula

$$\frac{\nu_2 - \nu_1}{\nu_1} = (1 + \alpha) \frac{U(\vec{x}_2) - U(\vec{x}_1)}{c^2}$$

Self-Gravity in QM?

The SN-equation

Gravitational collapse

Conclusions

- ▶ **Universality of Free Fall** is tested by measuring the Eötvös factor for two different materials A and B . Typical modern results on macroscopic test bodies are:

$$\eta(A, B) = 2 \cdot \frac{|a(A) - a(B)|}{a(A) + a(B)} < 10^{-13}$$

- ▶ **Local Lorentz Invariance** is tested by, e.g., modern versions of the Michelson-Morley experiment (isotropy of two-way speed of light). Typical modern results using microwave cavities are:

$$\frac{\Delta c}{c} < 10^{-16}$$

Note that Michelson-Morley experiments do not cover preferred lightlike directions, which are much harder to detect (Cohen & Glashow 2006).

- ▶ **Universality of Gravitational Redshift**. Still best test to date is 1976 comparison of two maser clocks (Gravity-Probe-A), one of which boosted to an altitude of 10 000 km by a Scout rocket:

$$\alpha < 7 \times 10^{-5}$$

This is clearly the weakest part of EEP. However, recent re-interpretations by Müller, Peters, and Chu (Nature 2010) of some 10-year old gravimeter experiments by Peters, Chung, and Chu using Caesium-based atom interferometers claim improvement by factor 10^4 (\rightarrow more below).

Gravitational collapse

Conclusions

Figure: Gedankenexperiment by NORDTVEDT to show that energy conservation connects anomalous redshift and violation of WEP. Considered are two copies of a system that is capable of 3 energy states A , B , and B' (blue, pink, and red), with $E_A < E_B < E_{B'}$. Initially system 2 is in state B and placed a height h above system 1 which is in state A . At time T_1 system 2 makes a transition $B \rightarrow A$ and sends out a photon of energy $h\nu = E_B - E_A$. At time T_2 system 1 absorbs this photon, which is now blue-shifted, and makes a transition $A \rightarrow B'$. At T_3 system 2 has been dropped from height h with acceleration g_A , has hit system 1 inelastically, leaving one system in state A and at rest, and the other system in state B with an upward motion with kinetic energy $E_{\text{kin}} = M_A g_A h + (E_{B'} - E_B)$. The latter motion is decelerated by g_B , which may differ from g_A . At T_4 the system in state B has climbed to the **same** height h by energy conservation. Hence have $E_{\text{kin}} = M_B g_B h$ and therefore $M_A g_A h + M_{B'} c^2 = M_B c^2 + M_B g_B h$, from which we get

$$\frac{\delta\nu}{\nu} = \frac{(M_{B'} - M_a) - (M_B - M_A)}{M_B - M_A} = \frac{g_B h}{c^2} \left[1 + \frac{M_A}{M_B - M_A} \frac{g_B - g_A}{g_B} \right] \quad (1a)$$

$$\Rightarrow \alpha = \frac{M_A}{M_B - M_A} \frac{g_B - g_A}{g_B} =: \frac{\delta g/g}{\delta M/M} \quad (1b)$$

One-particle Schrödinger wave in homogeneous force-field

Some basic issues concerning quantum mechanics and gravity

Domenico Giulini

Proposition: ψ solves the Schrödinger Equation

$$i\hbar\partial_t\psi = \left(-\frac{\hbar^2}{2m_j}\Delta - \vec{F}(t) \cdot \vec{x} \right) \psi$$

iff

$$\psi = (\exp(i\alpha)\psi') \circ \Phi^{-1},$$

where ψ' solves the free Schrödinger equation (i.e. without potential).

$\Phi : \mathbb{R}^4 \rightarrow \mathbb{R}^4$ is the following spacetime diffeomorphism (preserving time)

$$\Phi(t, \vec{x}) = (t, \vec{x} + \xi(t)).$$

ξ is a solution to

$$\ddot{\xi}(t) = \vec{F}(t)/m_j$$

with $\vec{\xi}(0) = \vec{0}$ and $\alpha : \mathbb{R}^4 \rightarrow \mathbb{R}$ is given by

$$\alpha(t, \vec{x}) = \frac{m_j}{\hbar} \left\{ \dot{\xi}(t) \cdot (\vec{x} + \vec{\xi}(t)) - \frac{1}{2} \int^t dt' \|\dot{\xi}(t')\|^2 \right\}.$$

Airy function

- ▶ Return-time for particle with energy E ejected at $z = z_i$ upwards far from classical turning point shows no corrections due to tunnelling, unlike for other potential shapes (corrections $\propto 2d/v$). Have (Davies 2004):

$$T_{\text{ret}} = 2 \cdot \left[\frac{m_i}{m_g} \right]^{\frac{1}{2}} \cdot \left[\frac{2h}{g} \right]^{\frac{1}{2}}, \quad h = (E/m_g g) - z_i.$$

- ▶ Eigen-energies (with hard wall at $z = 0$) and penetration depth are:

$$E_n = \left[\frac{m_g^2 g^2 \hbar^2}{2m_i} \right]^{\frac{1}{3}} \cdot (-z_n), \quad d = \left[\frac{\hbar^2}{2m_i m_g g} \right]^{\frac{1}{3}}.$$

The NR propagator

- ▶ For polynomial Lagrangians of at most quadratic order the propagator has the exact representation

$$K(z_b, t_b; z_a, t_a) = F(t_b, t_a) \exp \left\{ \frac{i}{\hbar} S_*(z_b, t_b; z_a, t_a) \right\}$$

where $F(t_b, t_a)$ does not depend on the initial and final position and S_* is the action for the extremising path (classical solution).

- ▶ Here we take

$$L(z, \dot{z}) = \frac{1}{2} m_i \dot{z}^2 - m_g g z$$

and get for parabolic path with downward acceleration g' ($= gm_g/m_i$)

$$\begin{aligned} S_{g'}(z_b, t_b; z_a, t_a) &= \frac{m_i}{2} \frac{(z_b - z_a)^2}{t_b - t_a} \\ &\quad - \frac{m_g g}{2} (z_b + z_a)(t_b - t_a) \\ &\quad + \frac{g'}{24} (t_b - t_a)^3 (m_i g' - 2m_g g) \end{aligned}$$

Terms in red ($\propto m_g$) originate from the potential part, those $\propto m_i$ from the kinetic part.

Self-Gravity in QM?

The SN-equation

Gravitational collapse

Conclusions

Figure: Spacetime paths followed by the atoms in the experiment of Kasevich and Chu. Raman pulses occur at times 0 , T , and $2T$ with four-momenta $p_1 = \hbar(-k_1 \vec{e}_z, \omega_1)$ and $p_2 = \hbar(k_2 \vec{e}_z, \omega_2)$. The insert shows the atomic level scheme and the directions of the laser beams. Transitions $g_1 \rightarrow g_2$ and $g_2 \rightarrow g_1$ are accompanied by four-momentum transfers $\Delta_{12}p = (-\kappa, \omega)$ and $\Delta_{21}p = -\Delta_{12}p$ respectively, where $\kappa = k_1 + k_2 > 0$ and $\omega = \omega_1 - \omega_2 > 0$.

Total phase shift

- ▶ For parabolic trajectories with downward acceleration g' ($g' = (m_g/m_i)g$ on solution paths), we get

$$\Delta\phi = \underbrace{\kappa T^2 g'}_{\Delta\phi_{\text{time}}} - \underbrace{\kappa T^2 (m_g/m_i) g}_{\Delta\phi_{\text{redshift}}} - \underbrace{\kappa T^2 g'}_{\Delta\phi_{\text{light}}}$$

- ▶ Here g is not measured. It is eliminated through a nearby reference measurement of the acceleration $\bar{g} = (M_g/M_i)g$ of a corner cube of inertial mass M_i and gravitational mass M_g .
- ▶ Using the Nordtvedt parameter for the atom-cube pair,

$$\eta := \eta(\text{atom, cube}) := 2 \frac{(m_g/m_i) - (M_g/M_i)}{(m_g/m_i) + (M_g/M_i)},$$

we get for the total phase shift :

$$\Delta\phi = -\kappa T^2 \bar{g} \frac{2 + \eta}{2 - \eta} \approx -\kappa T^2 \bar{g} (1 + \eta).$$

Total phase shift: Interpretation as test of UFF

Some basic issues concerning quantum mechanics and gravity

Domenico Giulini

- ▶ The results of Peters, Chung, and Chu (1999) were

$$\zeta_{\text{meas}} := \frac{-\Delta\phi}{\kappa T^2 c^2} = (1.090\,322\,683 \pm 0.000\,000\,003) \times 10^{-16} \cdot \text{m}^{-1},$$
$$\zeta_{\text{pred}} := \bar{g}/c^2 = (1.090\,322\,675 \pm 0.000\,000\,006) \times 10^{-16} \cdot \text{m}^{-1}.$$

- ▶ This implies an upper bound on UFF violations of

$$\eta(\text{atom, cube}) = \frac{\zeta_{\text{meas}}}{\zeta_{\text{pred}}} - 1 < (7 \pm 7) \times 10^{-9},$$

which is more than four orders of magnitude worse (higher) than the lower bounds obtained by more conventional methods using classical bodies.

- ▶ But Müller, Peters, and Chu (2010) interpret the findings of Peters, Chung, and Chu (1999) quite differently ...

Total phase shift: Interpretation as UGR

Some basic issues concerning quantum mechanics and gravity

Domenico Giulini

- ▶ Since $\Delta\phi_{\text{time}} + \Delta\phi_{\text{light}} = 0$, Müller, Peters, and Chu say

$$-\kappa T^2 g = \Delta\phi = \Delta\phi_{\text{redshift}}.$$

- ▶ Then have

$$\Delta\phi = \omega \Delta T = -\omega T \frac{\Delta U}{c^2} = -\omega T \frac{g \Delta h}{c^2} = -\omega T \frac{g \hbar \kappa}{m_j c^2} T = -\frac{\omega}{\omega_C} \kappa T^2 g$$

- ▶ Hence clocks must tick at Compton frequency!!!
- ▶ Being at the 10^{-9} level this interpretation - if tenable - would imply an improvement of UGR tests by a factor of 10^4 .
- ▶ This would be achieved by measuring the redshift in the gravitational field of the Earth over a distance of 0.12 mm.
- ▶ “The experiment thus confirms local position invariance by excluding anomalous variations of more than 7 parts in 10^{28} in the frequency of the Compton clocks. This corresponds to comparing the elapsed times to $\approx 10^{-29}$ sec.”
- ▶ Exercise: Can that be?

A precision measurement of the gravitational redshift by the interference of matter waves

Holger Müller^{1,2}, Achim Peters³ & Steven Chu^{1,2,4}

In summary, we improved the precision of measurements of the gravitational redshift by a factor of 10,000. This compares favourably to the European Space Agency's ACES mission, where it is anticipated that the gravitational redshift can be tested to a precision of 2 p.p.m. (ref. 5). Moreover, the distance scales of our tests (micro-

Conclusions regarding Müller *et al.*

- ▶ The standard expression

$$\Delta\phi = -\kappa g T^2$$

is uncontroversial.

- ▶ It also seems to be uncontroversial that a violation of UFF will modify it to

$$\Delta\phi = \kappa g T^2 \bar{g}(1 + \eta)$$

- ▶ Given Nordtvedt's Gedankenexperiment, this entails a dependence on α , albeit suppressed by $\delta M/M$ according to (1b).
- ▶ However, in case of violations of UGR, Müller *et al.* direct proportionality to $(1 + \alpha)$:

$$\Delta\phi = -\kappa g T^2 \bar{g}(1 + \alpha)(\dots)$$

The theoretical justification of this is, in my opinion, missing.

Conclusions

Self-Gravity in QM?

The SN-equation

Gravitational collapse

Conclusions

- ▶ The Schrödinger-Poisson system (as approximation to semi-classical Einstein equation)

$$i\hbar \frac{\partial \Psi}{\partial t} = \left(-\frac{\hbar^2}{2m} \Delta + m\Phi \right) \Psi$$
$$\Delta \Phi = 4\pi G m |\Psi|^2$$

- ▶ A stable ground state exists (Lieb 1977), which is of energy (Tod et al. 1998-2003)

$$E_0 = -0.163 \frac{G^2 m^5}{\hbar^2} = -0.163 \cdot mc^2 \cdot \left(\frac{m}{m_P} \right)^4$$

- ▶ For $m < m_P = 10^{19}$ u this is well bounded away from black hole formation and the Newtonian approximation can be trusted.

The time-dependent SN-Equation

- ▶ Time evolution of rotationally symmetric Gauß packet of initial width 500 nm. Collapse sets in for masses $m \gtrsim 4 \times 10^9 u$, but collapse times are still very long indeed.
- ▶ This is a 10^6 correction to earlier simulations by Carlip and Salzman (2006), though not outrageously beyond experimental reach.
- ▶ More in D.G. & A. Großardt: Classical and Quantum Gravity 28 (2011) 195026.

Conclusions

- ▶ No effect of self-gravity on quantum mechanical systems have so far been seen in laboratories.
- ▶ The Schrödinger-Newton equation can be derived from the Einstein-Klein-Gordon or Einstein-Dirac system in a NR approximation.
- ▶ It leads to inhibitions of dispersion, albeit in mass-widths ranges drastically different (less favourable) from that anticipated in Carlip & Salzman 2006.
- ▶ However, the interpretation of the SN-equation and its applicability to reduced centre-of-mass motion of single molecules is unclear. (Rather, self-gravitating condensate?)
